

FACTSHEET FOR SOUTHWEST PARTNERSHIP FIELD VALIDATION TEST

| | | | |
|---|--|---|--|
| Partnership Name | | Southwest Regional Partnership on Carbon Sequestration | |
| Contacts: DOE/NETL Project Mgr. | Name William O'Dowd | Organization NETL | E-Mail William.ODowd@NETL.DOE.GOV 1-412-386-4778 |
| Principal Investigator | Brian McPherson | SWP | brian@nmt.edu 1-801-581-5634 |
| Field Test Information: Field Test Name | Southwest Jurassic/Triassic Deep Saline Sequestration | | |
| Test Location | La Veta, Colorado | | |
| Amount and Source of CO ₂ | Tons 2.9 Million tons | Source 400,000 tons from CBM operation; remainder from Farnham Dome (natural source) | |
| Field Test Partners (Primary Sponsors) | Savoy Energy, LLC | | |
| | Pure Petroleum, LLC | | |
| | Blue Source, LLC PacifiCorp Southern California Edison | | |
| Summary of Field Test Site and Operations: | | | |
| <p>SWP plans to accomplish two sequestration deployments. The first stage deployment will occur at the La Veta Field in the Raton Basin in Colorado. This test will follow an injection schedule over 4 years, leading up to 900,000 tonnes (1,000,000 U.S. tons) of CO₂ per year. The second stage will occur in Wyoming's Green River Basin and will total 90,000 tonnes (100,000 U.S. tons) of CO₂ injected in a one year period. The target formation is the Entrada Formation of Jurassic age in both the Raton Basin in Colorado and the Green River Basin in Wyoming. Should the Jurassic Entrada have insufficient injectivity, the Triassic and Permian formations below the Jurassic are also great candidates for sequestration. By carrying out two tests in the same formation in different states, portability of science and engineering results may be evaluated.</p> | | | |
| Injection Site Description | | | |
| <p><i>Colorado Site:</i> The La Veta field injection site is located in the northwest corner of the Raton basin, 20 miles west of Walsenburg, in Huerfano County in south-central Colorado. This 6000 acre field was discovered in 1997 and is under development. Because La Veta is an active gas field, the state of access is commercial with no physical impediments to impact the project. It is not located on wetland or a sole-source aquifer where injection or monitoring wells will penetrate.</p> | | | |
| <p><i>Wyoming Site:</i> SWP suggests that the best location for the Green River Basin CO₂ injection deployment is the Rock Springs uplift, the site of the Jim Bridger power plant, owned and operated by PacifiCorp Energy. The Jurassic Entrada is capped by thick confining layers, and the injection site is at its most shallow depth underneath the Bridger power plant (~7,000 feet depth). The sites near this locale that SWP is investigating are owned by the Bureau of Land Management, with no physical impediments to impact the project. They are not located on wetland or sole-source aquifers where injection or monitoring wells will penetrate. Injection here will not begin until late 2009, providing some time to identify an optimum injection well location in the area.</p> | | | |

Description of Geology

The target formation is the Entrada Formation of Jurassic age in both the Raton Basin in Colorado and the Green

| Era | System and Series | Stratigraphic unit | Hydrogeologic unit | | | |
|-----------------------|----------------------|-------------------------------|--------------------------------------|-----------------------|---------------------|----------------|
| | | | | | | |
| Cenozoic | Quaternary | Unnamed alluvium | Local aquifers | | | |
| | Tertiary | Miocene | | Browns Park Formation | | |
| | | Oligocene | | Bishop Conglomerate | | |
| | | Eocene | | Bridger Formation | | |
| | | | | Green River Formation | Laney Member | Confining unit |
| | | | | | Wilkins Peak Member | Laney aquifer |
| | Tipton Shale Member | | | | | |
| Lyman Member | | | | | | |
| Paleocene | Wasatch Formation | Saline aquifer | Confining unit | | | |
| | Fort Union Formation | | Wasatch-Fort Union aquifer | | | |
| Mesozoic | Cretaceous | Mesaverde Group | Saline aquifer | Mesaverde aquifer | | |
| | | Baxter Shale | Confining Shales | Confining unit | | |
| | | Frontier Formation | | | | |
| | | Mancos and Mowry | | | | |
| | | Bear River Formation | | | Muddy Sandstone | |
| | | Thermopolis Shale | | | | |
| | | Dakota Sandstone | Saline aquifer | | | |
| | Jurassic | Morrison Formation | Confining shale | | | |
| | | | Saline aquifer | | | |
| | | Curtis-Stump Formations | Confining shales | | | |
| | | Entrada Sandstone | Saline aquifer | | | |
| | | Gypsum Spring Formation | Confining unit | | | |
| | Triassic | Navajo-Nugget Sandstones | Saline aquifers | | | |
| | | Chugwater Formation | Confining unit | Confining unit | | |
| | | Dinwoody Formation | | | | |
| Phosphoria Formation | | | | | | |
| Paleozoic | Permian | Tensleep Sandstone | Pennsylvanian Sandstone aquifer | Pennsylvanian aquifer | | |
| | | Amsden Formation | Saline aquifer | Unnamed | | |
| | | Confining unit | | | | |
| | Mississippian | | Saline aquifer | Mississippian aquifer | | |
| | | Madison Limestone | Mississippian Carbonate-rock aquifer | | | |
| | Devonian | Darby Formation | Confining unit | Unnamed | | |
| | Silurian | | Paleozoic aquifers | | | |
| | Ordovician | Bighorn Dolomite | | | Local aquifer | |
| | | | | | | |
| | Cambrian | Gallatin Limestone | | | Confining unit | |
| Gros Ventre Formation | | | | | | |
| Flathead Sandstone | | Local aquifer | | | | |
| Precambrian | | Igneous and metamorphic rocks | Precambrian confining unit | Confining unit | | |

Figure 1. Generalized stratigraphic column for the SWP region of interest.

River Basin in Wyoming. The Entrada Formation is a deep saline unit present throughout the Southwest Partnership region, as well as in many states outside the region. The formation contains mudstones, claystones, and siltstones, as well as lenticular sandstone beds, limestone, and conglomerate. Below the Entrada are more excellent candidate reservoirs of Triassic and Permian age. In all cases, the seal is the Morrison Formation, a thick (400 feet) shale/gypsum/siltstone of Jurassic age, also regionally present throughout the Southwest Partnership states. At both sites, the unit lies within a true “stacked” system (Figure 1)—above the Entrada/Morrison combination lies the Dakota formation, a Cretaceous-aged sandstone similar to the Entrada and capped by the Pierre/Mancos shale, a very thick (1,500 feet to 5,000 feet) shale unit. The SWP has gathered porosity, permeability, mechanical, compositional, and geophysical data associated with these target reservoirs and seals.

The Raton Basin was formed during the Laramide orogeny as tectonic activity caused uplift of the Sangre de Cristo Mountains. This created numerous folds and faults throughout the basin. The western margin of the basin is highly deformed, with large numbers of faults and fractures. Also, Tertiary volcanism led to additional faulting across the western side of the Sangre de Cristo Mountains. At the western margin near the site, location fractures are directly linked to the thrust fold along the western edge of the basin. As a whole, the northern section of the Raton Basin is more stable and less faulted than the southern portions. The Deployment Phase well location has very few significant faults in the vicinity;

however, the proximity of the western basin edge and the compressional faulting at the Sangre de Cristo Mountain thrust front create a need for careful identification of faults and fractures near the injection well.

Source of CO₂

Colorado site: For the Raton Basin deployment site, the source of CO₂ is a natural gas processing plant, located in the La Veta field. This plant uses a non-amine membrane process for separating CO₂ and vents over 360,000 tonnes (400,000 U.S. tons) per year to the atmosphere. Production at La Veta is slated to increase, which will double the amount of CO₂ to over 730,000 tonnes (800,000 U.S. tons) per year in the near future. A short pipeline will need to be added to facilitate injection of captured CO₂ into the Entrada underneath the gas-processing plant.

The CO₂ captured will be 97% pure, with the remainder nitrogen (air). Should this source be insufficient for the tests, the CO₂ will be drawn from the Sheep Mountain source and pipeline, 16 miles away from the injection site.

Figure 2. Schematic of injection well design.

Wyoming site: For the Green River basin test, the actual injection site will not be selected until the Deployment Phase begins, with injection slated to begin in 2009. However, the SWP anticipates the best location for injection to be coincident with the location of the Jim Bridger Power Plant in Rock Springs, Wyoming, a power plant owned and operated by PacifiCorp, a SWP partner. Accordingly, the most promising source of CO₂ for this deployment is ExxonMobil's Shute Creek Facility (La Barge plant in southern Wyoming), a source of anthropogenic CO₂. According to the Wyoming Pipeline Authority, Exxon's Shute Creek facility serves as the supply source for all CO₂ enhanced oil recovery projects within Wyoming. A 24-inch CO₂ pipeline runs from the Shute Creek Facility to Rock Springs. The CO₂ at Shute Creek is high grade (~97% pure).

Injection Operations

For the Raton Basin site in Colorado, a minimal length of pipeline will be added in order to deliver the CO₂ into the Entrada formation through a deep well. Blue Source LLC, a SWP partner, and Manzano LLC, the field operator, are completing and connecting a pipeline from the La Veta injection site to the Sheep Mountain pipeline. Upon completion of the deployment phase test, this pipeline will be used to transport the captured CO₂ from the La Veta field to the Permian Basin enhanced oil recovery market. Figure 2 represents the planned general well design for injection operations.

For the Green River basin deployment, detailed injection operations will be determined based on final designation of the injection site.

Characterization Data

Because the Raton and Green River sites are in areas of active petroleum generation, the amount and quality of characterization data is fairly good.

Research Objectives:

SWP's overall goal is to validate the information and technology developed under the Characterization and Validation Phases relative to research and field activities, public outreach efforts, and regional characterization. Specific objectives include:

- Develop an overall methodology that optimizes engineering and planning for future commercial-scale sequestration projects.
- Conduct successful large-scale CO₂ injection projects targeted at the Entrada Formation.
- Achieve a more thorough understanding of the science, technology, regulatory framework, risk factors, and public opinion issues associated with large-scale injection operations.
- Validate monitoring, mitigation, and verification (MMV) activities; modeling, and equipment operations.

- Refine capacity estimates of the target formation using results of the test.

Summary of Modeling and MMV Efforts: (Use the table provided for MMV)

The project will require extensive monitoring and simulation to determine if the storage operations are effective in trapping the injected CO₂ for millennia. Vertical seismic profiling and microgravity methods will be particularly utilized, given their proven ability to resolve the size of the CO₂ plume. Monitoring, mitigation and verification (MMV) techniques that will be used include repeat 3D seismic surveys, pressure monitoring, groundwater chemistry monitoring, pressure and fluid sample monitoring from other locations, soil gas sampling, and other methods. A variety of “in house” and commercial/public simulation tools will be used, including GEM, TOUGH2, TOUGHREACT, FEHM, CO₂-PENS, COMSOL, THRUST3D, MRKEOS and SWEOS.

Table 1 summarizes the monitoring approaches planned for the SWP Phase III deployment program.

Table 1. Monitoring options in the planning stages of SWP’s Phase III deployment project.

| Measurement technique | Measurement parameters | Application |
|--|---|---|
| Introduced and natural tracers | Travel time | Tracing movement of CO ₂ in the storage formation |
| | Partitioning of CO ₂ into brine or oil | Quantifying solubility trapping |
| | Identification sources of CO ₂ | Tracing leakage |
| Water composition | CO ₂ , HCO ₃ ⁻ , CO ₃ ²⁻ | Quantifying solubility and mineral trapping |
| | Major ions | Quantifying CO ₂ -water-rock interactions |
| | Trace elements | Detecting leakage into shallow groundwater aquifers |
| | Salinity | |
| Subsurface pressure | Formation pressure | Control of formation pressure below fracture gradient |
| | Annulus pressure | Wellbore and injection tubing condition |
| | Groundwater aquifer pressure | Leakage out of the storage formation |
| Well logs | | Tracking CO ₂ movement in and above storage formation |
| | Brine salinity | Tracking migration of brine into shallow aquifers |
| | Sonic velocity | Calibrating seismic velocities for 3D seismic surveys |
| | CO ₂ saturation | |
| Time-lapse 3D seismic imaging | P and S wave velocity | Tracking CO ₂ movement in and above storage formation |
| | Reflection horizons | Detecting detailed distribution of CO ₂ in the storage formation |
| | Seismic amplitude attenuation | Detection leakage through faults and fractures |
| Vertical seismic profiling and crosswell seismic imaging | P and S wave velocity | Development of microfractures in formation or caprock |
| | Reflection horizons | CO ₂ migration pathways |
| | Seismic amplitude attenuation | |
| Passive seismic monitoring | Location, magnitude and source characteristics of seismic events | Tracking movement of CO ₂ in and above the storage formation |
| | | Detecting migration of brine into shallow aquifers |
| | | Detect CO ₂ movement in or above storage formation |
| Electrical and electromagnetic techniques | Formation conductivity | CO ₂ mass balance in the subsurface |
| | Electromagnetic induction | |
| Time-lapse gravity techniques | Density changes caused by fluid displacement | |
| | | |

| | | |
|--|--|---|
| Land surface deformation Visible and infrared imaging from satellite or planes CO ₂ land surface flux monitoring using flux chambers or eddy covariance | Tilt Vertical and horizontal displacement using interferometry and GPS Hyperspectral imaging of land surface CO ₂ fluxes between the land surface and atmosphere atmosphere | Detect geomechanical effects on storage formation and caprock Locate CO ₂ migration pathways Detect vegetative stress Detect, locate and quantify CO ₂ releases Detect elevated levels of CO ₂ Identify source of elevated soil gas CO ₂ Evaluate ecosystem impacts |
| Soil gas sampling | Soil gas composition Isotopic analysis of CO ₂ | |
| Accomplishments to Date: Site characterization is under way, and general scoping calculations (using model simulations) are being carried Out to design monitoring surveys (Table 1). | | |
| Summarize Target Sink Storage Opportunities and Benefits to the Region: SWP's Characterization and Validation Phase analyses determined that the region's point sources emit approximately 320 million tonnes (350 million U.S. tons) of CO ₂ per year, which for 100 years (assuming no change in emissions rate) translates to 32 billion tonnes (35 billion U.S. tons) total storage capacity needed. SWP's Characterization and Validation Phase analyses provide an initial estimate of capacity of the Entrada saline reservoirs for just five selected basins in the Southwest region to exceed 18 billion tonnes (20 billion U.S. tons), well over the 50% criterion. During the Deployment Phase, SWP will continue to refine capacity estimates and evaluate injectivity and other critical factors relevant to regional storage goals. | | |
